

Project Ventana

Enabling an AI-Powered Workforce to Achieve Maximum Productivity

ACCTC 2026 · Pima Community College · June 2026

Presented by Matt Borja

Session Summary

What it is: A proven agentic workflow framework that connects LLM agents (GitHub Copilot, Claude Code) to a shared enterprise knowledge base via a lightweight, stdio-based MCP server — requiring no infrastructure beyond Git and Node.js.

How it works: A small MCP server runs locally on each developer's machine. It exposes two tools — **ventana-list** and **ventana-read** — that give the AI agent direct, read-only access to a Git-hosted knowledge base over HTTPS, authenticated transparently via the developer's existing Git credential helper.

Why it matters: Grounding agents in authoritative, domain-specific content eliminates hallucinations and calibrates every response to the team's actual environment — not generic trained approximations.

What teams gain: Corpus searches that took hours complete in seconds. Agents write and run tests, connect to databases, perform end-to-end parity checks, and automate infrastructure tasks — all within a single session.

Deployment footprint: No centralized gateway. The server component is a single Git repository; the client is a handful of files copied into each developer's project workspace. Access control is enforced entirely at the Git host layer.

[PLACEHOLDER — Full slide deck coming soon]

*This file will be replaced with the finalized conference slides. To be notified when the slides and future updates are published, **Watch this repository** on GitHub (use Watch → All Activity or Releases Only depending on your preference). Early previewers who star or watch the repository will receive*

notifications as new material is committed.
